Click here for latest version

Abstract. What is the impact of student loans on post baccalaureate choices? Using within-cohort across-college variations in financial aid policies, we find that higher levels of debt induce a front loading of earnings, an underinvestment in human capital and an earlier entry into home ownership. We then estimate a life-cycle model using a representative panel of college graduates and analyze the mechanisms behind the interaction between student debt, career choices and housing. Our results indicate that lower net wealth generates a trade-off between career and housing choices for college graduates. Finally, we compare alternative policy proposals. Relative to the baseline 10-year fixed repayment plan, an income based repayment plan increases human capital accumulation and earnings growth, while postponing entry into home ownership. Importantly, linking repayments to income achieves outcomes that are close to what can be achieved by a more ambitious student loan forgiveness plan.

1 Introduction

Student loans have become the new normal for bachelor’s degree recipients in the United States. Between 1993 and 2016, the percentage of students who had borrowed at any time during their undergraduate years rose from 45 percent for 1993 graduates to 68 percent for 2016 graduates (Figure 1). Among borrowers, the median cumulative amount borrowed rose from $13,000 to $27,000 in real terms, with 25% of graduating seniors having borrowed more than $40,000 in 2016. Student borrowing is now more likely to be a burden for a higher percentage of college graduates and a relevant factor they take into account in their economic and financial decisions.

In presence of credit constraints, student debt affects post graduation choices by making further borrowing more difficult. As the relative value of current consumption grows, and workers postpone additional human capital investment, a series of life cycle decisions are consequently affected. We highlight one often overlooked cost of additional investment in human capital, that is the postponing of home-ownership. When this channel is taken into account, the initial impact of student debt on lifetime earnings is amplified, as the relative value of additional human capital investment decreases throughout the life cycle due to strong horizon effects induced by homeownership.

We use the Baccalaureate and Beyond Longitudinal Study (B&B), a restricted access dataset compiled by the National Center for Education Statistics. The B&B surveys cover a representative sample of U.S. college graduates interviewed on successive waves. In order to empirically examine how college borrowing affects career choices, earnings, and wealth accumulation in the years after graduation, we need to overcome notorious identification problems, as the amount borrowed may be determined by unobserved individual ability or different expectations, which in turn would affect all post graduation choices.

We address the identification problem by introducing an instrument based on variations in colleges’ financial aid. Composition of aid at the college level is calculated using public access data from the Integrated Postsecondary Education Data System (IPEDS). We focus on institutional grants, which are funded from private sources and net assets of the institution and experience significant variations year-by-year. We use these supply changes in financial aid during college enrollment to extract variation in student debt that is not correlated with post bachelor choices through unobserved characteristics. We also show that institutional grant changes are not correlated with college measures of quality.

Our empirical results suggest that lower net wealth induces a trade-off between career and housing choices for young workers. Higher levels of student debt cause a front loading of earnings, while significantly and persistently deterring additional human capital investment (measured as graduate school enrollment). This, in turn, contributes to lower earnings growth. Indebted graduates earn 0.29% more for each

---

1Most of the increase in student debt has been attributed to the substantial rising cost of college over the last decade (see Looney and Yannelis (2015)). Since 2004, tuition at four year colleges increased at an average rate of 3% per year. Increasing federal loan limits as well as a relaxation of eligibility criteria helped to moderate the impact of higher costs on college enrollment.
percentage increase in student debt in the first year. Over time, this effect is compensated by wage growth being 0.1% lower. Surprisingly, we also find that higher levels of student debt generate an earlier entry into home ownership for college graduates.

We develop a model with endogenous (risky) human capital accumulation enriched by career choices and housing decisions to rationalize the empirical evidence and understand the importance of credit constraints in shaping post graduation outcomes. After graduating from college, individuals enter the labor market and are heterogeneous in innate ability, human capital, liquid wealth and student debt. They sequentially decide on human capital investment, savings, non housing and housing consumption while they pay for student debt. At any point, they can enroll in a post bachelor program and, if they do, take on additional student debt. Workers can buy a house through a 30-year fixed-rate mortgage as long as they make a down-payment and their debt payments do not exceed a proportion of their income.

Our theoretical framework implies that, because of introducing debt-funded human capital and post-college housing credit constraints, student debt plays a key role in explaining earnings inequality throughout the life cycle. College graduates with higher student debt sort into careers with lower compensation for human capital accumulation, and then experience lower earnings growth.

The model is estimated by Simulated Method of Moments using a combination of data from B&B and Current Population Survey (CPS). Structural estimation highlights substantial non-monetary returns to post bachelor education, that yields
consumption-equivalent utility consisting of more than $30,000 per year. On the other hand, skill premium for the post bachelor degree educated workers corresponds to less than 40% of the earnings differential with respect to workers with just a bachelor degree. Individuals with relatively higher ability are thus able to afford the cost of higher education given the mentioned composition of returns, while others postpone or choose the alternative career path. Credit constraints in the housing market for highly leveraged households is crucial in determining these results.

The model also speaks to the effects of borrowing on home ownership. Unconstrained graduates who choose a career with a steeper earnings path (as is the case for those who enroll in graduate programs) are at the same time more likely to postpone their investment in housing. On the other hand, workers that choose to remain in a career that implies lower earnings growth consider housing a relatively more attractive investment. Hence, home ownership is relatively higher for young graduates that started their career with more student debt, a finding consistent with our empirical results.

These results point to an easy counterfactual exercise that helps highlighting the way in which, conversely, housing affects enrolment patterns. In a model without home ownership, distortions to human capital accumulation induced by student debt are smaller, enrolment in post bachelor programs is higher, and income inequality decreases. The main reason for this effect is that postponing homeownership is costly: higher debt forces graduates to postpone additional education, or to invest less in human capital to accumulate higher savings. While doing so, workers realize that enrolling at a later age would mean a further postponement of homeownership, as the downpayment and/or debt-to-income constraints will bind for an even longer period of time, and choose give up on additional education and choose careers with a flatter income profile.

Finally, we use the model to evaluate the impact of a widespread adoption of an income based repayment plans (IRP) and compare it to a forgiveness plan. We find that the introduction of the IRP provides the foundation for reducing the unintended consequences of student loan debt. By lowering an individual’s monthly payments, IRP provides a consumption smoothing mechanism that reduces the need to choose a higher paying job. The implementation of a forgiveness plan and the widespread adoption IRP yield similar outcomes, both increasing enrollment in graduate programs and earnings over the life cycle. In both cases, however, alleviating the debt burden does imply a delay in homeownership. This is particularly true in the case of IBR, due to a combination of increased post bachelor degree attendance, longer time horizon for debt repayment, and higher overall repayments for borrowers with higher balances.

The paper is organized as follows. Section 2 summarizes the literature, Section 3 describes the data and presents the empirical results, Section 4 provides an overview of the model and the life cycle choices of individuals, Section 5 calibrates and estimates the model to observed data patterns, Section 6 presents the main results of the model, Section 7 analyzes policy counterfactuals, and, Section 8 concludes with some policy discussion and future work.
2 Related Literature

Isolating the effects of student debt on post graduate choices is made complex by student debt being typically negatively selected, as pointed out by Looney and Yannelis (2015). The empirical evidence on how student debt affects earnings mostly points to a positive relationship, at least in the short run\(^2\). Based on a natural experiment in an elite university, Rothstein and Rouse (2011) show that student debt causes college graduates to choose jobs with an initial higher salary and reduces the probability that they choose "public" low paid jobs. Luo and Mongey (2019) find that a version of these results generalizes to the cross section of the U.S. colleges. In particular, they find that higher student debt causes college graduates to take jobs with higher wages, lower job satisfaction, and more on the job search.

Using a difference-in-difference approach, Gerald and Smythe (2019) study the impact of student debt on various labor market outcomes (income, hourly wages, and hours worked). They conclude that indebted students have initial higher earnings due to higher work hours rather than higher wage rates. Chapman (2015) finds that exogenously increasing the loan burden of a college graduate by $1,000 increases their income by $400-$800 one year after graduation. Field (2009) shows that law students who were offered loans were more likely to accept jobs in higher paying corporate law rather than public interest law.

Nonetheless, higher initial earnings may not necessarily lead to higher lifetime earnings if they are not followed by further human capital investment (Becker (1962), Ben-Porath (1967), Hause (1972) and Mincer (1974)). In this line of thought, Fos, Liberman and Yannelis (2017) investigate the effects of student debt on additional human capital investment measured as graduate school enrollment. They find that a $4,000 increase in student debt reduces the likelihood of enrollment in graduate school by 1.5 percentage points. In this paper, we contribute to this literature by considering general labor market outcomes for a nationally representative sample of college graduates. We also provide a unified framework for analyzing the relationship between student debt, earnings and human capital investment after college.

Another set of empirical articles have analyzed the role of student loans on first time home ownership. Controlling for multiple factors, Houle and Berger (2015), Cooper and Wang (2014) and Gicheva and Thompson (2014) show that student debt reduces the likelihood of homeownership for young households. Using administrative data and tuition induced variation in student debt, Bleemer et al. (2020) find that the recent increase in student debt could explain between 11 and 35 percent of the decline in young’s homeownership over 2007-2015. Using a similar approach, Mezza et al. (2020) estimate that a $1,000 increase in student debt decreased first time homeownership by approximately 1.5 p.p. for public 4-year college graduates who left school between 1997 and 2005.

Our analysis also relates to the literature that study student loan program design within a quantitative framework. For example, Ionescu (2009) finds that repayment flexibility increases college enrollment significantly, whereas relaxation of eligibility

\(^2\)For empirical studies that conclude a negative or neutral effect of student debt on earnings see: Weidner (2016), Akers (2012), Zhang (2013).
requirements has little effect on enrollment or default rates. In a similar framework, Ionescu and Simpson (2016) find that tuition subsides increase aggregate welfare by increasing college investment and reducing default rates in the private market. Johnson (2013) also shows that tuition subsidies provide larger increases in college enrollments than increasing borrowing limits. Compared to this literature, our model provides a more detailed characterization of college graduates career choices and post schooling wealth accumulation.

In a related paper, Di Maggio, Kalda and Yao (2019) examine the effect of student debt forgiveness on individual credit and labor market outcomes. Using hand collected lawsuits filings matched with individual credit bureau information, they find that borrowers experiencing the debt relief shock reduce their overall indebtedness by 26%. They also find that borrowers’ probability to change jobs increase after the discharge and this leads to an increase in earnings by more than $4000 over a three year period. We examine the effects of an hypothetical student debt forgiveness plan on both earnings and first time home ownership.

Finally, our paper relates to the literature that analyzes how initial conditions affect lifetime earnings inequality. In particular, this literature focuses on the importance of initial conditions relative to shocks over the life cycle. Hugget, Ventura and Yaron (2011) study how heterogeneity in initial wealth and human capital affect lifetime inequality by modelling earnings growth through a Ben-Porath production function. They find that initial conditions, as measured at age 23, determine more than 60 percent of variation in lifetime utility, and that the majority of this variation is determined by initial human capital differences. In a similar framework, Heathcote, Storesletten and Violante (2014) use a model with heterogeneous preferences and productivity, and find instead that life cycle productivity shocks account for half of the cross sectional variance of wages.

The role of initial conditions in shaping long term human capital accumulation has been addressed in the search and matching literature as well. Using a model with directed search and heterogeneous asset holdings, Griffy (2019) finds that initial wealth plays a crucial role in determining life cycle inequality, and heterogeneity in skills has a relatively smaller impact. This difference is caused by the inclusion of frictional labor markets, which makes wealth have a first order effect on earnings. In a similar vein, Eeckhout and Sepahsalar (2019) show that there is positive sorting between workers with net asset holdings and more productive firms. Finally, our model is also related to the one in Athreya et al. (2019), as they build a life cycle model of college choice where agents are assumed to be heterogeneous in ability, liquid assets and human capital to understand the returns to college attendance for various segments of the population.

In this article, we focus on college graduates and also find that initial wealth (in particular, student debt) plays a crucial role in life cycle decisions. Differently from this strand of literature, we model the labor market as career paths with different (debt-funded and risky) human capital requirements. We also include housing as a mechanism through which career choices could interact with credit constraints and affect lifetime earnings.
3 Data and Empirical Analysis

3.1 Description of Data

Our main source of data comes from the restricted use dataset from the National Center for Education Statistics (NCES) Baccalaureate and Beyond Survey (B&B). The survey follows several cohorts of bachelor’s degree recipients over time and contains a mix of administrative and self reported data about their income, student debt, occupation, graduate school enrollment and homeownership (among other variables).

B&B draws its cohorts from the National Postsecondary Student Aid Study (NPSAS), which collects data from large, nationally representative samples of postsecondary students and institutions to examine how students pay for postsecondary education. B&B samples are representative of graduating seniors in all majors and colleges. Our analysis focuses on the most recently available cohort (2007/08), which was followed up one and four years after graduation and was interviewed again in 2018 (forthcoming). We also use as robustness students that graduated from college in 2016 and were followed one and four years after graduation (forthcoming).

Source: Baccalaureate and Beyond Longitudinal Study (B & B 2008/2012), CPS 2009-2012, and IPEDS.
We restrict the sample to traditional college students: students who attended only one college, enrolled between 2002 and 2004, and graduated at age 21-24. In terms of colleges, we focus on four year public and private non-profit colleges, excluding private for-profit and special focus institutions. After imposing these restrictions, we also remove all colleges for which we do not have more than 3 students - this is necessary since we use an instrument that is based on college level variation and we need enough students per college for the sample to be representative.

Table 1 provides the main statistics for the whole sample and for the restricted sample. The table also provides CPS statistics for individuals with at least a BA degree and aged 22-25 in 2009 and 25-28 in 2012. Measures of earnings for Baccalaureate & Beyond for college graduates are similar to the ones in Census: the average earning for a college graduate in the restricted sample was $30,282 1 year after college, while $41,380 four years after graduation. Around 40 percent of college graduates owned a house and 22 percent had a Graduate Degree by 2012.

In order to understand the role of career sorting and its relationship with earnings and entry into home ownership, we characterize career paths based on workers’ educational attainment using the Current Population Survey (CPS). As we can see in Figure 2a, college graduates with a graduate degree typically have much higher earnings growth. However, their initial earnings after graduation are similar to those with a Bachelor’s degree (with a high percentage of post-BA graduates taking on graduate student debt). Indeed, educational choices are inextricably linked with housing choices: Figure 2b shows that workers investing more in human capital have significantly lower initial home ownership rates.

Figure 2: Earnings and Homeownership by Educational Attainment

(a) Median Earnings  
(b) Homeownership

Figure 2 shows median annual earnings and average homeownership by age for workers with a graduate degree (in red) and with a bachelor’s degree (in blue). Source: Current Population Survey (CPS, 2000-2020) - males with at least a Bachelor’s Degree.
3.2 Empirical Estimation

Isolating the causal effect of student debt is challenging, as borrowing is hardly an exogenous variable in students’ decisions. The bias could go in either direction. On the one hand, if low ability students are less likely to receive grants, $\beta$ will reflect the latent negative correlation between ability and borrowing. On the other hand, students with higher earnings expectations could be more willing to borrow, resulting in debt being positively selected. Using the same reasoning, if colleges with lower instructional expenditure per student have a higher incidence of debt, then $\beta$ will also capture lower college quality.

In order to obtain an unbiased estimate of the causal effect of student debt, the regression should include all of the college and individual characteristics that affect the amount borrowed during college and the post baccalaureate decision. To address this issue, we group colleges into different categories based on their sector (public or private non-profit), selectivity (minimally, moderately, very selective), and their Carnegie Classification (Doctorate granting Universities, Master’s or Baccalaureate Colleges).

In addition, we also include a rich set of individual controls. We use individual characteristics that are included in the FAFSA financial aid application form (expected family contribution and dependency status), the year they started college (2002, 2003 or 2004), gender and ethnicity. We also include the SAT score and the major of study in order to account for individual’s ability.\(^3\)

Thus, the relationship between debt and post college outcomes can be expressed in the following reduced form Equation:

\[
y_{i,t+\tau} = \alpha_{j(i),t} + \beta d_{i,t} + \Gamma w_{i,t} + \epsilon_{i,t} (1)
\]

where $y_{i,t+\tau}$ is the individual’s post college outcome, $\alpha_{j(i),t}$ is the vector that captures college fixed effects, $d_{i,t}$ is the log of the cumulative amount of loans (federal and private) borrowed for undergraduate degree at time of graduation, and $w_{i,t}$ is the set of individual controls.

Nonetheless, unobserved students’ characteristics could still be relevant in determining access to different forms of aid and have a direct impact on students’ post baccalaureate decisions; this makes $d_{i,t}$ a potential endogenous variable, and thus, the OLS estimate of Equation (1) could still be biased.

3.3 Instrumental Variable: Institutional Grants

In this section, we show that supply side variations in the financial aid options faced by all students in a particular college offer a way to overcome the identification problem. In practice, students usually receive a year-by-year financial aid package that is determined by college financial aid officers, but is not known in advance at the time of application. It includes student loans, scholarships, and, grants from the government and the institution itself.

\(^3\)See Appendix 1 for more details about how these variables are defined.
Differently from government grants and student loans, institutional grants are funded from private sources and net assets of the institution. Since institutional grants do not require repayment, they are preferred to loans and are the first to be added into a financial aid package. Loans are therefore the marginal source of funds to most students. In order to capture this substitution between institutional grants and loans, we follow Luo and Mongey (2019) and compute the ratio of the value of total institutional grants issued by the college to the sum of grants and student loans (grant to aid henceforth):

\[
x_{j(i)} = \left( \frac{\text{inst.grant}_{j(i)}}{\text{inst.grant}_{j(i)} + \text{loan}_{j(i)}} \right) \cdot 100
\]

Figure 3 shows how variations in the grant to aid ratio capture the substitution between the two measures of funding for both public and private non-profit colleges. Nevertheless, the exclusion restriction may be violated if the grant to aid ratio is correlated with other college or individual characteristics and those characteristics have a direct impact on students’ post baccalaureate decisions. This may happen because students are not randomly assigned to a college and they choose college based on a bundle of college characteristics, which include financial aid availability.

Figure 3: Institutional Grants and Student Loans (2007/08)

(a) Public 4y Colleges

(b) Private non-profit 4y Colleges

Figure 3 shows the average amount of institutional grants (in blue) and student debt (in red) by grant-to-aid for 4-year public and private non-profit colleges in the 2007/2008 academic year, respectively. Source: U.S. Department of Education, National Center for Education Statistics, Integrated Postsecondary Education Data System (IPEDS) (2007/08). Colleges are weighted by full-time first-time students enrollment.
In order to reduce this source of bias, we exploit variation in grant to aid policies during college enrollment. These changes (Figure 4) are likely unexpected for the student at the enrollment stage and might come from surprise returns to university endowments, unexpected large donations and/or changes in college costs.

We thus take as our instrument the average variation in grant to aid during college enrollment (where \( t_0(i) \) represents the year when the individual first enrolled):

\[
z_{j(i)} = \bar{x}_{j(i)} - x_{j,i,t_0(i)} = \frac{\sum_{t=t_0(i)+1}^{T} x_{j,i,t}}{T - t_0(i) - 1} - x_{j,i,t_0(i)}
\]

The amount of college debt is modeled as an outcome of individual demand for debt and these supply side college variations in institutional grants, represented by:

\[
d_{i,t} = \mu_{j(i),t} + \delta z_{j(i)} + \Pi w_{i,t} + u_{i,t} \tag{2}
\]

We estimate the model by two stage regression. Therefore, it is important that there is significant variation of the instrument with student debt across institutions. Table 2 shows that such condition is satisfied. The results imply that, on average, a change in 10 percentage point in grant to aid during college enrollment induces a corresponding 30% decrease in student debt, all else equal. These yearly variations in financial aid policy are also uncorrelated with college quality characteristics (Table A1).

Figure 4 shows the relationship between the change and level of grant-to-aid. Colleges are weighted by the amount of full-time first-time students enrolled. Table 2 shows the regression output of the first-stage regression. Source: U.S. Department of Education, National Center for Education Statistics, Integrated Postsecondary Education Data System (IPEDS 2007/08) and Baccalaureate and Beyond Longitudinal Study (B & B 2008/2012).

3.4 Empirical Results

This section presents our main empirical results. We show the causal effect of student loans on earnings one, four and ten (forthcoming) years after college graduation. At the same time, we analyze the role of debt on other post baccalaureate choices intrinsically linked to earnings such as graduate school attendance and housing. We use the estimation strategy proposed in the previous section, which produces a Local Average Treatment Effect (LATE), that is, the effect of student debt on the subset of compliers (colleges that changed grant to aid policies while our sample of students were enrolled).

Results from the estimation of Equation (1) on earnings are given in the first two columns of Table 3. The first column shows the OLS and IV estimates for earnings one year after bachelor’s degree completion. Column (1) implies that, on average, increasing a student’s debt by 30% (roughly a $7,000 increase) would lead to an increase in annual earnings of 9%. Column (2) runs the same equation on earnings growth 4 years after graduation and shows that the effect turns significantly negative: increasing a student’s debt by 30% would lead to a reduction in earnings growth of 3%.

The front loading effect of borrowing on earnings is thus consistent with the hypothesis that highly indebted graduates need to boost their initial earnings to ease the burden of repaying their loans. The negative growth on earnings might point to indebted workers under-investing in additional education after college.

Columns (3) and (4) show the relationships between student debt and post baccalaureate education. Column (3) shows the average marginal effects of debt on post BA attainment 4 years after graduation. *Ceteris paribus*, a 30% increase in college debt reduces the probability of having a post baccalaureate degree four years after graduation by 1.5 percentage points. In addition, Column (4) shows the average marginal effect of debt on cumulative post BA enrollment since college graduation. As we can see, more indebted students do not catch up on graduate enrollment even four years after graduation.

Measuring the impact of student loans on first entry into home ownership is an important piece for validating our main hypothesis. Consistent with our previous results, a 30% increase in college debt increases the probability of being home owner by 1.5 p.p. (Column (5)). Such a positive relationship with housing is consistent with indebted students working more initially after graduating and under-investing in (risky debt-funded) additional human capital.

4 The Model

Our empirical estimates show that more indebted graduates front load earnings and give up graduate school, but tend to access home ownership relatively earlier. How is this possible? The crucial factor, as we will show, is that imperfect credit markets create a trade-off between career and housing that, at certain values of parameters and debt, is consistent with our empirical findings.

4.1 A simple 2-period model

We assume a deterministic two period model in which workers can only choose in a binary fashion between two careers (i.e. graduate school or not, $\beta \in \{B,G\}$), and between buying a house or not ($H \in \{0,1\}$) without any access to the credit market$^4$. Homeowners ($H=1$) receive a utility premium ($v_H$), but they have to pay for the housing price in the first period ($p$). If workers choose to go to graduate school ($\beta = G$) they find themselves in a steeper earnings profile: they receive lower earnings in the first period ($w^-$) but higher earnings in the second period ($w^+$). For simplicity, we assume no monetary cost for graduate school and, thus, no additional student loans. Workers with student debt ($d$) maximize the following inter-temporal utility problem:

$$
V(d) = \max_{\beta,H} \log(c_1) + \log(c_2) + \log(v_H)H
$$

$$
c_1 = w_1(\beta) - pH - d, \quad w_1(B) = w, \quad w_1(G) = w^- < w
$$

$$
c_2 = w_2(\beta), \quad w_2(B) = w, \quad w_2(G) = w^+ > w
$$

$^4$We are indebted to Alistair Macaulay for suggesting us a way to discuss our results under this simple two-period model.
This formulation yields simple analytic expressions for indirect utility and parameter ranges for each career and housing choice. Let’s first consider the decision of a worker to choose to go to graduate school ($\beta = G$) conditional on his housing decision (we normalize $w$ to 1). The worker follows a threshold rule:

$$d < d^*_\beta = \begin{cases} \frac{w^--w^-}{w^-1} - p, & \text{if } H = 1 \\ \frac{w^--w^-}{w^-1}, & \text{if } H = 0 \end{cases}$$

This implies that given the housing choice ($H$), workers are less likely to choose the steep career path as student debt rises. At the same time, homeowners are less likely to go to graduate school ($d^*_\beta(H = 1) < d^*_\beta(H = 0)$). This happens as the decision to go to graduate school while being homeowner pushes further down consumption in the first period, increasing $U'(c_1)$. Hence, going to graduate school is more expensive in utility terms. On the other side, conditional on career choice, a recent college graduate chooses to buy a house ($H = 1$) if:

$$d < d^*_H = \begin{cases} w^- - \frac{pvH}{v_H-1}, & \text{if } \gamma = G \\ 1 - \frac{pv_H}{v_H-1}, & \text{if } \gamma = B \end{cases}$$

In a similar vein, this implies that given the career choice ($\beta$), workers are less likely to buy a house as student debt rises and buying a house is more expensive in utility terms for those who attended graduate school. But, as these choices are taken jointly, there will be four distinct regions for the first period discrete action: $\{H = 1, \beta = 1\}$, $\{H = 0, \beta = 1\}$, $\{H = 1, \beta = 0\}$, and $\{H = 0, \beta = 0\}$. We will denote the threshold value for each as $d^*_{\beta,H}$. In particular, our empirical findings are consistent with the following:

**Proposition 4.1:** Assume the first period costs of graduate school ($\beta = G$) are larger than the cost of buying a house, i.e. $w^- - w^- > p$. Then, for middling values of debt, workers will choose housing over graduate school ($d^*_{G,0} < d^*_{B,1}$).

To prove the result, it is sufficient to use the four thresholds introduced above. As we can see in Figure 5a, for very low values of student debt, workers choose both to go to graduate school and buy a house, while for very high levels of debt workers choose to stay as renters and the flat career profile. However, there is a region of intermediate debt values for which increasing balances induces workers to give up graduate school and buy a home. Hence, $U'(c_1)$ rises faster for lower $c_1$. However, as Figure 5b shows, flattening the graduate school earnings profile yields the opposite outcome: for intermediate debt values, increasing student loan balances induces workers to give up home ownership.

The existence of this result strongly depends on the assumption of imperfect financial markets. In the next section, we analyze this career - housing trade-off using a life cycle model with more dimensions of heterogeneity. In addition, we add (1) idiosyncratic shocks, (2) monetary cost (and amenity value) to attend graduate school (which implies more student debt), and, (3) imperfect mortgage market.
4.2 The life-cycle Model

The model described in this section builds on important contributions to the human capital literature, as the career choice model of Keane and Wolpin (1997) and the Ben-Porath (1967) model presented in Huggett, Ventura and Yaron (2011), extended to include student debt and housing. The aim is to build a richer model that not only replicates the intuition of the previous section, but can also be used to perform counterfactual analysis.

A unit measure of college graduates enter the labor market in each period and are heterogeneous in ability (a), human capital (h), liquid wealth (k) and student debt (d). Each household lives for T periods deterministically. During working age, workers can decide to enroll in grad school: if they do, they access a different career path. Workers also sequentially decide labor and human capital investment within their career, savings and housing and non housing consumption while they pay for student debt (if any).

4.3 Setting

Preferences. Each agent maximizes expected lifetime utility over non durable consumption (c) and housing services (s) (see Kaplan, Mitman and Violante (2019)):

\[
u(c, s) = \frac{(\zeta_1 s^1 - \zeta_1)^{1-\sigma}}{1 - \sigma}\tag{1}\]

where c>0 and s=1+\zeta_2, and \zeta_2 is the housing service from owned housing.
**Labor Income.** When individuals work, hourly earnings are priced competitively to reflect their marginal productivity. Assuming a representative firm that uses human capital from workers in both careers, earnings are given by the human capital augmented number of hours worked, multiplied by the equilibrium rental rate ($R_t$).

$$w_{j,t}(l_t, h_t) = R_t h_t^{\beta_j}$$

(2)

Workers are also exposed to unemployment risk: they can be separated from their job with probability $\rho$; while unemployed, they earn home production $b$, but cannot invest in human capital. When workers retire, they are assigned pension transfers that are proportional to their last earnings.

**Careers and human capital.** We restrict career choice to two different paths. In each career path, their compensation is equal to the marginal product of hours. Formally, normalizing rental rate $R_t = 1$, we get hourly wage $\hat{w}_{j,t} = h_t^{\beta_j}$, with $j = \{B, G\}$. The two paths differ in how workers’ human capital accumulation translates into productive human capital. Human capital is less productive ($\beta_B < \beta_G$) for workers without graduate school education. Therefore, assuming workers make identical human capital investments, differences in earnings would grow as workers accumulate human capital.

After the career choice is made, individuals sequentially choose how much hours to work ($l_t$) and invest in further human capital ($1 - l_t$). Human capital evolves according to the following Ben-Porath law of motion:

$$h_{t+1} = e^{\gamma_{t+1}}(h_t + a((1 - l_t)h_t)^{\alpha}), \quad z_{t+1} \sim N(\mu_z, \sigma_z^2)$$

(3)

which depends on individual’s ability ($a$) and with risk coming from human capital idiosyncratic shocks. The Ben-Porath formulation implies that switching to the “steeper” career path that follows graduate school has three contrasting effects on human capital investment decisions. On the one hand, since earnings in the steeper career path loads more on human capital, investments are riskier.

Additionally, higher marginal product of human capital gives weaker incentives for graduate school educated worker to invest in human capital because of a simple wealth effect. On the other hand, $\beta_G > \beta_B$ generates a strong substitution effect, in that every unit of consumption today that is foregone in order to invest in human capital generates higher returns in the future. The third effect seems to be dominant in the data, suggesting that difference in career paths are amplified by endogenous human capital investment.

**Graduate School.** Individuals can enroll in graduate school until age 32: if they do, they attend for $S$ periods, and then start to work in their new career. While enrolled, human capital grows in every period at rate $\gamma$, and workers pay tuition ($p_g$) and consume using a combination of their liquid savings ($k$) and graduate student loans ($d_g$). They also get non monetary utility $\xi$, which is the amenity value of being in school as opposed to working.
Financial Markets. Agents can save in liquid assets \( k \). Workers are allowed to borrow short term, using the rate \( r_{-} \), but they face a credit card borrowing constraint that can depend on their current income \( (\phi) \). If \( k > 0 \), savings yield a constant risk free rate \( r_{+} \).

Student Loans. There are several options for repaying student loans, but the traditional and still most common is the 10-year fixed payment plan. Similar to a mortgage, the borrower makes constant payments over 120 months until the balance of principal and interest is paid off. Student loan payments \( (P_d) \) can be obtained as:

\[
P_d = \frac{d_0}{\left(1 + r_d \right)^{10} - 1} \left(1 + \frac{r_d}{1 + r_d} \right)
\]

where \( d_0 \) is the student debt at the time of college graduation and \( r_d \) is the gross interest rate on student loans. If a worker enrolls in graduate school, payments are suspended while enrolled and graduate school debt is added to the students’ balance. After graduation, undergraduate and graduate student debt is consolidated and a new standard repayment plan is started, giving the worker 120 months to repay the full amount.

Housing. Workers can buy a house at any moment of their life - except when they are enrolled in graduate school - as long as their life span is long enough that they can cover the 30-year mortgage and they have enough liquid assets to use as a downpayment. Workers are also subject to housing preference shocks, which capture shifts in life events (household formation or divorce). We model those shifts as taste shocks, i.e. additively separable choice specific random taste shocks, and assume they are i.i.d. Extreme Value type I distributed with scale parameter \( \sigma_\varepsilon \). If a worker chooses not to own their house, she has to rent \( (P_r) \). The rental price is tied to the price of the house, \( P_o \), and is set to match a given price to rent ratio. Individuals can ask for a 30-year fixed mortgage \( (m) \) to pay the price of the house \( (P_o) \).

There is no possibility of default or asking for a second mortgage. Home ownership is treated as an absorbing state, so if an individual is homeowner in a given year, then it will stay as homeowner at all future dates.

At the time of buying the house, individuals face two borrowing constraints: (1) they must make a downpayment \( (1 - \lambda) \), (2) their monthly debt payments (student and mortgage debt) cannot exceed a proportion of their income \( (\psi) \). We assume that both constraints must be enforced at origination only.

Home owners must always pay the mortgage payment \( (P_m) \) until mortgage balances are zero, following:

\[
P_m = \frac{(1 - \lambda)p_h}{R_{m}^{30} - 1} \left(1 + \frac{R_{m}}{1 + R_{m}} \right)^{-30}
\]
4.4 Recursive formulation

We will illustrate the problem for agents of different stages of life, as the recursive formulation will differ according to it. The unit of time is a semester. The choice is motivated by several facts: it corresponds to the length of the initial grace period (when student loan payments must not be made), it allows for a reasonable accounting of separation risk, and yet it reduces the time dimension enough so that we can solve and estimate the model.

We write future values in recursive expressions by adding a $t$ to them. The choice-specific value functions are denoted indicating the discrete state - for instance, $V^g$ indicates the value function of the worker with post-bachelor degree education.

Retired workers:

At retirement age $t = t_R$, workers are assigned pension transfers ($p$) that are proportional to their last earnings ($w = w_{t_R-1}$). Retired workers make consumption and saving decisions using their savings from working age ($k_{t_R-1}$). If they are home owners ($o$), they have to pay the residual parts of their mortgage ($m$) in equal payments ($P_m$) until mortgage debt is fully paid off. Otherwise, if they are renters ($r$), they need to rent and pay $P_r$ every period. Retired workers cannot buy a house, as mortgage duration exceeds their life expectancy. We assume no bequests and terminal condition for liquid assets to be equal to zero. Finally, we impose a non-negativity constraint on consumption on all agents.

Recursive Problem for renters, for $t = t_R, ..., T$, is:

$$V_{r,t}(a, w, k) = \max_{k'} u(c, s) + \beta V_{r,t+1}(a, w, k')$$ (6)

$$c + k' + P_r = (1 + r) \cdot k + pw$$

$$m_T = 0, k_T = 0, k' \geq \phi(pw), c \geq 0,$$

The Problem for home owners for $t = t_R, ..., T$, with mortgage payment $P_m$ is:

$$V_{o,t}(a, w, k, m) = \max_{k', m'} u(c, s) + \beta V_{o,t+1}(a, w, k', m')$$ (7)

$$c + k' + P_m = (1 + r) \cdot k + pw$$

$$m' = (1 + r_d)m - P_m \geq 0$$

$$k_T = 0, k' \geq \phi(pw), c \geq 0$$

In both cases, $r = r_+$ if $k \geq 0$, and $r = r_-$ otherwise.
Workers:

Agents enter working age \((t = 1,...,t_{R-1})\), and face two discrete choices every period: which career to pursue, i.e. whether to enroll in graduate school \((j = \{B,G\})\), and whether to buy a house or not \((H = \{r,o\})\). In both cases, workers are subject to preference shocks - respectively, denote the preference shock for the housing choice as \(\sigma_{\varepsilon_H}\), and the preference shock for the schooling choice as \(\sigma_{\varepsilon_j}\). Both preference shocks are i.i.d. Extreme Value type I distributed with scale parameter \(\sigma_{\varepsilon}\).

Workers’ problem entails saving and choosing how much hours to work \((l)\) and invest in further human capital \((1-l)\) in every period. Human capital investment is risky and subject to an independent and identically distributed idiosyncratic shock every period \((z)\). Earnings are given by the human capital augmented number of hours worked multiplied by the equilibrium rental rate as defined in (2).

There is also unemployment risk: while working \((u = 0)\), they can be exogenously separated from their job with probability \(\rho\); while unemployed \((u = 1)\), they earn home production \(b\), but cannot invest in human capital, so that \(h' = h\). In order to apply for a mortgage and thus become a homeowner, workers have to satisfy the down-payment constraint (governed by the ratio \(\lambda\)) and at the same time satisfy the debt to income constraint (determined by the value \(\psi\)). Once the mortgage is approved, the payments \((P_m)\) are fixed for the next 30 years as defined in (5).

Workers that enter the labor market with any positive amount of student debt \((d_0 > 0)\) are by default enrolled in a 10-year fixed rate repayment plan and don’t have the option of defaulting or deferring on student loan payments.

For notational convenience, we can collect shocks and exogenous states in \(e = \{\varepsilon_H, \varepsilon_j, u\}\), and all the other idiosyncratic states in \(x = \{a, h, k, d\}\), where \(d\) indicates residual student debt balances. The recursive problem for renters without graduate school education, while employed, is thus:

\[
V_{r,t}^B(x, e) = \max_{k', l} \left\{ u(c, s) + \sigma_{\varepsilon B,r} + \beta \mathbb{E}[\tilde{V}_{t+1}^B(x', e')] \right\} 
\]

\[
c + k' + (P_r + P_d) = (1 + r) \cdot k + w_B(l, h) \\
h' = e' \cdot (h + a((1 - l)h)^\alpha) \\
d' = (1 + r_d)d - P_d \geq 0 \\
k' \geq \phi, \ c \geq 0
\]

where:

\[
\mathbb{E}[\tilde{V}_{t+1}^B(x', e')] = \mathbb{E} \left[ \max \left\{ V_{r,t+1}^B + \sigma_{\varepsilon B,r} + \sigma_{\varepsilon G,r} + \sigma_{\varepsilon B,o} \right\} \right] 
\]

and \(V_{B}^G\) and \(V_{o}^B\) are the value function of a worker enrolled in grad school and homeowner, respectively. Unemployed workers’ problem is analogous, with earnings replaced by \(b\) and no human capital investment decision. Unemployed workers can find a job in the same career with probability \(1 - \rho\).
Home owners with housing payment $P_m$ face the following problem:

$$V_{o,t}^B(x,e) = \max_{k',l} \left\{ u(c,s) + \sigma \epsilon_{B,o} + \beta \mathbb{E}[V_{t+1}^B(x',e')] \right\}$$

(9)

$$c + k' + (P_m + P_d) = (1 + r) \cdot k + w_B(l,h)$$

$$h' = e^x(h + a((1 - l)h)^\alpha)$$

$$d' = (1 + r_d) d - P_d \geq 0$$

$$m' = (1 + r_d) m - P_m$$

$$P_m = \begin{cases} \lambda p_h, & \text{if } m = 30 \cdot P_m \\ \frac{r_a(1+r_d)30(1-\lambda) p_h}{(1+r_d)30-1} & \text{if } m < 30 \cdot P_m \end{cases}$$

$$k' \geq \phi, \quad c \geq 0, \quad \frac{P_m + P_d}{w_B} \leq \psi$$

where:

$$\mathbb{E}[\tilde{V}_{t+1}^B(x',e')] = \mathbb{E} \left[ \max \left\{ V_{o,t+1}^B + \sigma \epsilon_{B,o}, V_{o,t+1}^G + \sigma \epsilon_{G,o} \right\} \right]$$

If the worker is in the first period of home ownership, $P_m$ equals to the downpayment required to buy the house. After that period, housing payments are determined by the mortgage equation (5), as before.

At this point we want to characterize the recursive problem of the individual attending graduate school. For simplicity, we will characterize only the problem of the renter. Define $\tilde{S}$ as the number of periods required to get the degree. For $s \leq \tilde{S}$:

$$V_{r,t}^G(x,e,s) = \max_{k'} \left\{ u(c,s) + \xi + \sigma \epsilon_{G,r} + \beta \mathbb{E}[\tilde{V}_{t+1}^G(x',e',s')] \right\}$$

(10)

$$c + k' + a = (1 + r) \cdot k + d_g$$

$$h' = (1 + g) \cdot h$$

$$d' = (1 + r_d) \cdot d + d_g \cdot \mathbbm{1}_{s=1}$$

$$k' \geq 0, \quad c \geq 0$$

We assume that, during graduate school, the borrowing constraint with liquid assets is tighter - since the individual is not working she has to keep her liquid assets positive. When $s > \tilde{S}$, the recursive problem is analogous to the problem of a worker with student loans, conditional on career earnings’ slope $\beta_G$. 

20
5 Calibration and Estimation

In this section, we discuss how we determine the parameters required for the analysis. We set these parameters in two ways. First, we set some parameters from elsewhere in the literature or by using data estimation (Table 4). The remaining parameters are estimated using indirect inference through the model.

5.1 External Parameters

Timing. Each period time in the model represents two quarters. Individuals start making decisions when they graduate from college. After finishing college, they start working and repaying their student debt. Agents retire at the age of 65 and die when they are 80.

Preferences. Preferences are set using standard calibration in the macroeconomics literature. The yearly discount factor is set to be 0.99. We set the constant relative risk aversion in the utility function to 2.

Career and Human Capital. Following Huggett, Ventura and Yaron (2011), we set the mean shock of human capital to -0.029, with 0.111 variance and the production function parameter \( \alpha \) to 0.66. We assume that, when unemployed, worker gains access to unemployment benefits that sum up to \( b \) calibrated to the Federal poverty threshold for an individual living alone in 2008 ($991 USD a month).

Labor Income. We set the rental rate to a yearly rate of 5% of the house price, and pension to be 45 percent of the last earned income. Finally, exogenous separation risk is set to 6 percent per year for bachelor-educated workers, and 4.5 percent for workers with a post-Bachelor degree, matching the average number of employment to unemployment transition of the two groups (see Menzio, Telyukova and Visschers (2016)).

Financial Markets and student debt. The annual interest rate for student loans and a 30-year fixed rate mortgage is calibrated to the 2004-2008 average rate of 6 percent. The risk free interest rate for savings is set at 0 following null real returns after 2008 and credit card borrowing rate is fixed at an annual 10 percent. We set a credit card borrowing limit of -$5,000, targeting a median rate of credit limit to annual labor income for college graduates of 20 percent.

Housing. We set the price of the house at the average home price in the U.S. ($250,000) during the years 2008-2012. The rental price is set to match the price to rent ratio (0.02). The parameters that determine the LTV and DTI are chosen to match institutional features of the US mortgage market. For the LTV parameter, fix a downpayment constraint of \( 0.15 \cdot P_o \). This value is intended to reflect the distribution of the LTV in Freddie Mac data, which has two masses point around 80% and 90%, where the first mass point is typically populated by younger buyers and thus seems more appropriate for pinning down the problem of first home ownership (see Greenwald (2018)). In order to qualify for a Qualified Mortgage under CFPB guidelines, a borrower’s total debt to income ratio, including the mortgage payment and all other recurring debt payments, cannot exceed 43 percent.

5.2 Distribution of Initial Characteristics

In order to simulate the model, we have to make parameter choices regarding starting values of liquid assets, ability, human capital and student debt.

While college graduates typically do not have substantial wealth of their own, they may have access to alternative sources of wealth that are not directly measured. We assume students leave college with zero liquid assets, but receive an exogenous transfer from their parents. We use the Expected Family Contribution (EFC), with an average transfer of $16,309 (\mu_k)$ and a standard deviation of $16,321 (\sigma_k)$. We also use B&B data for the student debt distribution. We use an average debt balance of $16,619. This figure is composed by a percentage of 66% of borrowers, with cumulative average balances of $25,048 (\mu_d)$ and a standard deviation of $18,223 (\sigma_d)$. We also take the correlation between parental transfers and student debt of $-0.17 (\rho_{k,d})$.

Following Huggett, Ventura and Yaron (2011), we assume that the distribution of ability and human capital is jointly log normally distributed. We calibrate the initial mean ($\mu_h$) and standard deviation ($\sigma_h$) of human capital to match the mean and standard deviation of earnings one year after graduation from B&B data - respectively

$^{5}$The EFC is calculated according to a formula established by law. Student’s family’s taxed and untaxed income, assets, and benefits (such as unemployment or Social Security) are considered in the formula.
at $34,554 and $20,600. We calibrate the mean level of ability ($\mu_a$) in order to match a yearly average growth rate of earnings for college graduates of 3%. We take the correlation between human capital and ability ($\sigma_{a,h}$) from Athreya et al. (2019), who estimate a life cycle model of education choice and report a correlation of 0.67. Finally, we need to determine the correlation between ability and student debt ($\rho_{a,d}$). This parameter has an important interpretation because, if correctly identified, it informs about the bias that an econometrician would be subject to when estimating Equation (1) with least squares. We estimate this parameter, jointly with other structural parameters, to match the key properties of the earnings and homeownership profiles on CPS and B&B data.

5.3 Estimation

5.3.1 Simulated Method of Moments

Parameters $\Theta = \{\xi, \gamma, \beta_g, \zeta_1, \zeta_2, \rho_{a,d}\}$ are jointly estimated by Simulated Method of Moments (see Gourieroux, Monfort and Renault (1993), Smith Jr (1993) and Gallant and Tauchen (1996)). Let $x_i$ be an i.i.d. data vector, $i = 1, \ldots, n$, and $y_i(\Theta)$ be an i.i.d. simulated vector from simulation $s$, so that $i = 1, \ldots, N$, and $s = 1, \ldots, S$. The goal is to estimate $\Theta$ by matching a set of simulated moments, denoted as $h(y_{i,s}(\Theta))$, with the corresponding set of actual data moments, denoted as $h(x_i)$. Define:

$$g_n(\Theta) = \frac{1}{n} \left[ \frac{1}{S} \sum_{i=1}^{n} h(x_i) - \frac{1}{S} \sum_{i=1}^{S} h(y_{i,s}(\Theta)) \right]$$

(11)

Building $g_n(\Theta)$ in this case faces an important challenge. In classic SMM estimation, exploration of the state space requires the model to be solved more than 10000 times. In the case of a model with a large state space like ours, this could be very computationally expensive. To overcome the curse of dimensionality, we discretize the parameter space using sparse grids (see Bungartz and Griebel (2004)). A similar approach in structural modelling has been using in the context of maximum likelihood estimation, see for instance Heiss and Winschel (2008).

By using functions with support restricted to a neighborhood of each point to build $h(y_{i,s}(\Theta))$, our approach is suitable for approximating the parameter-moment mapping even in cases of sharp behavior, like large fluctuations of the gradient (see Stoyanov (2013)). Having $h(y_{i,s}(\Theta))$ at hand, we can construct an objective function that looks like:

$$\hat{\Theta} = \arg \min_{\Theta} g_n'(\Theta) \hat{W}_n g_n(\Theta)$$

(12)

where $\hat{W}_n$ is a positive definite matrix that converges in probability to a deterministic positive definite matrix $W$. There are many feasible choices for the covariance matrix,

---

6 Using a cluster with 144 CPUs, we manage to obtain a full solution of the model and simulate it in about 14 minutes.
and it is common to simply rely on an identity matrix for $W$. To construct the optimal weight matrix, we use the influence function technique from Erickson and Whited (2002) (see also Bazdresch, Kahn and Whited (2017) for an application closer to our case). The derivation is explained in detail in Appendix 5. Finding a solution to (12) faces the issue of the possible presence of many local minima: to make sure our solution is robust, we restart our optimization routine using multiple sets of starting values. Each routine solves its problem using a Nelder-Mead algorithm. Having an estimate of $h(y_{i,s}(\Theta))$ also allows us to obtain standard errors of parameter estimates, as they can be calculated knowing that

$$aVar(\hat{\Theta}) = \left( 1 + \frac{1}{S} \right) \left[ \frac{\partial g_n(\Theta)}{\partial \Theta} W \frac{\partial g_n(\Theta)}{\partial \Theta'} \right]^{-1}$$

(13)

### 5.3.2 Identification

The model generates a large number of moments that can be used for estimation. Since interactions between each choice are quite complex, global identification is not possible even if one can attempt a one to one mapping between model parameters and empirical moments. Local identification, however, simply requires that the gradient of the model implied moments with respect to the parameter, $\partial h(y_{i,s}(\Theta))/\partial \Theta$, has full rank. This condition suggests that for a parameter to be identified, some subset of the vector of implied moments, must change when that particular parameter moves - see Bazdresch, Kahn and Whited (2017).

Source: Current Population Survey, years 2000-2020, individuals with at least a bachelor degree, age 23-40, working full time

**Table 5** shows the empirical moments we target in our estimation. We use the ratio of home ownership at age 40 by education groups, when the ratio is 1, as a target moment. The flow value of housing, $\zeta_1$ is identified by shifts in this ratio. The reason for this is that housing demand of workers with a post-bachelor degree is more sensitive to changes in the flow value: as it grows, not only less graduates enroll in post-bachelor
programs, but workers with additional education try to enter into home ownership earlier, thus matching the home ownership of workers that only have a bachelor.

We also use as a moment graduate enrollment at age 32. The most related parameter is the amenity value of graduate school (ξ): this is the value that mostly relates to the degree of sorting into additional education by ability, which in turn determines graduate school enrollment and the ratio of the constants in income profiles. Hence, we can also identify ξ by looking at shifts in the relative level of incomes between post-bachelor and bachelor-only educated workers. We use the ratio of the constant and the slope of life cycle earnings calculated from individuals aged 24-40 in Current Population Survey during years 2000-2020.

We want to know about the two earnings parameters; γ ultimately determines the value of attending a post-bachelor degree. In the model, it also affects sorting, enrollment, and overall home ownership. However, only the relationship with the constant term in the home ownership life cycle profile is monotonous; as γ grows, it first increases graduate school attendance. Then, it also starts to allow more indebted workers to postpone enrollment, and so the ratio decreases without affecting the ratio of the earnings profiles. The most straightforward identifying relationship is a result of higher γ simply increasing returns to graduate studies, thus allowing more workers to enter into home ownership at some point in time. More intuitively, the skill premium β\(_g\) identifies the ratio of debt to income. The reason is that the skill premium, besides affecting earnings, is the main reason for increasing or decreasing early enrollment (remember the debt to income ratio is taken at age 25) in the model.

Finally, we find that the correlation between debt and ability, ρ\(_{a,d}\) is clearly identified by the ratio in the slopes of life cycle profiles of earnings. This is also intuitive: as the relationship between debt balances and ability becomes stronger (i.e. more negative), sorting into post bachelor degrees will unambiguously increase, other things not varying much. Hence, our model implies that growth in earnings differentials are mostly coming from increased borrowing of graduates with lower learning ability.

Table 6 displays parameter estimates. The amenity value of graduate school is expressed in dollar terms, but does not correspond to ξ. To obtain it, we assume individuals in grad school are renters and have zero net liquid assets. Then the value is obtained by solving for the amount of consumption increase that would yield equivalent flow utility to grad school attendance. Standard errors, in the second column, tells us that estimates of parameters are precise - the only minor concern being represented by the objective function being less sensitive to changes in ξ.

Table 6: Estimated Parameters
5.3.3 Model Fit

The model replicates well overall earnings dynamics (Figure 6). The model matches pretty well average yearly income growth (1.9% in the data and 1.9% in our model), and earnings growth naturally slows because of income effects in the Ben-Porath problem. The patterns in enrollment replicates gradual entry into post graduate studies, and the level slightly more than a third of college educated workers pursuing further education. The slope in the life cycle pattern of home ownership in our model is higher than in the data: especially in early years, home ownership is substantially lower, and then it catches up later in the working life. This can be explained with the choice of abstracting from bequest shocks in the model, as they would allow households to bring forward home ownership by relaxing their budget constraint.

Decomposing the rate of home ownership by educational level, as done later in the text, we can see that the delay in purchases is almost entirely attributable to workers that pursue graduate studies. Another factor that limits earlier home purchases is our assumption of having just one size (and thus one price) available to workers. As results in the empirical section suggest, individuals who enter into home ownership earlier because college debt also purchase less expensive real estate. Extending the choice set by allowing individuals to differentiate their purchases with respect to price is the next step for improving the fit of our model to the data.

6 Results

6.1 The Role of Student Debt

There are two main trade-offs involved in the initial career choice. First, workers that not pursue additional education start with higher disposable income but then have lower income growth compared to the more human capital intensive careers. Second, income paths of bachelor educated workers are less volatile as human capital accumulation is a risky investment. Workers whose undergraduate borrowing is above the average level start with higher earnings, because they are most likely to be working rather than being enrolled. After some years, the sorting effects of student loans start to affect earnings, and thus create a wide and persistent earnings gap.

Table 7 shows the estimated impact of an increase in debt on earnings, education and housing and compares it with the empirical estimates from Section 3.4. In the model, indebted graduates have 0.13% higher earnings for each 1% of additional student borrowing, but 0.21% lower earnings growth in the following four years. The model also replicates well the impact of debt on graduate school attendance and homeownership.

![Table 7: Student Debt, Earnings, Career and Housing](image)

\[\Delta y_{t+4} \text{ is the 4-year growth in earnings after graduation}\]

In absence of frictions to borrowing, student loans should have no effect on career choices and human capital investment. In our model, the effects of student loans on career choices and lifetime earnings are ultimately the result of two main frictions. First, young workers face credit constraints that limit their ability to smooth durable and non-durable consumption. Second, student loans follow a predetermined fixed repayment schedule and alternative repayment schemes are limited\(^7\).

\(^7\)Our empirical analysis is focused on graduates that entered the labor market in 2008: during those years, less than 7% of borrowers enrolled in plans that allowed payments to be linked to earnings. After a series of reforms, enrollment in income based plans has increased substantially in the following decade.
Table 8 shows how entry into graduate school is affected by borrowing conditional on ability levels. More indebted students are significantly less likely to enroll. This happens for two reasons: on the one hand, while attending school allows to postpone payments, new debt is added to the existing one. Adding the burden of additional borrowing has compounding effects which put considerable pressure on future disposable consumption, thus discouraging enrollment. On the other hand, workers still have the possibility of starting to repay, while working, and then enrolling when their debt burden has reduced.

</tbody>
</table>

The value of switching, however, decreases with tenure due to a horizon effect: as the worker gets older, and approaches the age where it would be optimal to start a mortgage, attending graduate school would imply a postponement of entry into home ownership because of the binding credit constraint, reducing the value of additional education. Interestingly, the largest impact of borrowing on enrolment is on individuals with higher ability. A dampened sorting into careers points on the second effect being dominant: in fact, while relatively low ability individuals enroll smoothly over post graduation years, high ability individuals who would postpone getting additional education and switching career find the option becoming increasingly costly as they get older.

6.2 Lifetime Earnings

In order to understand the relative importance of different channels in affecting earnings over the life cycle, we decompose earnings growth differential between workers. To do so, we group workers based on different percentiles of student debt distribution. Notice one can obtain average earnings growth from Equation (3).

8 We are not modelling household formation, and thus we are missing a potential counterbalancing effect, represented by adding a second income stream. However, as suggested by empirical evidence in the previous section, the impact of student debt on household formation goes in the same direction as the effects on home ownership. Chang et al. (2019) points out that the recent decline in home ownership can be attributed to delayed household formation, providing additional support to the view that housing purchase and marriage can be considered as a joint choice.
Define $s_G$ as the share of post bachelor educated workers in a given group, $\bar{a}$ as the average ability and $F(h)$ as the distribution of human capital in that group. Average earnings growth will be defined as:

$$\Delta(w) = \int (s_G \beta_G + (1 - s_G) \beta_B) \bar{a} ((1 - l)h)^\alpha dF(h)$$

(14)

As argued above, highly indebted workers choose flatter earnings profiles. In Figure 7 we decompose the earnings growth differentials between the lowest and the highest tercile of workers ordered by undergraduate borrowing. Interestingly, ability plays a minor role in determining earnings growth differentials. This comes from two aspects. First, model estimates deliver small correlation between initial ability and debt. More importantly, though, there is ex post sorting that depends on the fact that human capital accumulation is risky at the individual level.

Figure 7: Decomposing Earnings Growth Differentials: Low versus High Debt

High ability - high debt individuals with good human capital realizations experience both high initial wage growth and lower rate of enrollment in post bachelor degrees, as the option value of switching career decreases substantially after their human capital (and thus earnings) reach a higher level, hence they stay in the labor force while workers with lower ability and the same realizations find enrollment more valuable and thus enroll (disappearing temporarily from the workforce). Differences given by skill premium are coming from different post bachelor degree attendance patterns, as highlighted in Table 8. As highly indebted students catch up on enrollment, the contribution of skill premium decreases, but remains positive and eventually becomes the main factor driving earnings growth differentials as human capital investment behavior reaches a plateau for most workers.

Finally, we find that endogeneous human capital accumulation contributes for the lion share of earnings growth differentials. Two effects go in the same direction in determining this result. As one can see from the policy function of workers for the Ben-Porath human capital investment choice, highly indebted workers simply choose to invest less in order to have higher earnings in the current period. This is reinforced by career choices, as the same investment has higher returns for workers that enjoy
a higher skill premium. This is consistent with earnings growth differentials being highest during the earlier years.

6.3 The Importance of Housing

In our model, student loans affect home ownership through two main channels. On the one hand, highly indebted students are less likely likely to pursue extra education, which has lower returns to human capital, thus lower expected growth but also lower income risk. Thus, housing is a relatively more attractive investment at the start of the working career. On the other hand, student loan borrowers might face more difficulties in satisfying both the downpayment and the debt to income requirements for a mortgage. Since student loan payments reduce workers’ disposable income, both investment in human capital and savings will be smaller. In addition, higher borrowing sorts workers into less human capital intensive careers, which negatively affects their lifetime earnings.

As shown in Table 9, all those effects play a decisive role in determining the age at which households purchase their first home. From the second row it is possible to see that, for those workers who don’t choose to enroll in graduate studies, borrowing affects home ownership mostly through the wealth effect. Hence, borrowers enter into home ownership later, with the delay growing nonlinearly in debt balances. In the aggregate, however, the role of post-bachelor enrollment dominates. As we can observe from the first row, the larger share of enrollment of non borrowers pushes home ownership to later in life. As balances grow, the two effects compensate each other.

</table>

\(a=\) includes those who do not enroll in grad school at any point in time

To understand how relevant the housing channel is in determining education and career choices, we compare model predictions in a counterfactual scenario when workers are not allowed to access home ownership and remain renters during their whole life.\(^9\) This way we are reducing available choices to workers compared to the baseline model, but we allow them to fully re-optimize given the new constraints they face. In this exercise, absent housing, agents can make different decisions about the timing of their investment in education (as well as about how much time to spend on human capital accumulation) than in the baseline.

\(^9\)An equivalent assumption is that we are imposing \(\zeta_2 = 0\) while leaving all other parameters unchanged from the baseline estimation

</tr>
</tbody>
</table>

Two clear trends emerge in Table 10: first, enrollment increases for both groups, and it does even more for those who borrowed less. Second, while highly indebted students still choose to postpone enrollment in order to reduce their debt balances, they do eventually enroll in the following years, while the baseline model suggests strong horizon effects. Switching costs (i.e. limited transferability of human capital) and borrowing constraints still matter, and determine the difference in enrollment patterns between graduates with different debt balances. Notice, however, that even in this context enrollment should not necessarily be identical along the debt distribution, to the extent that correlation with learning ability is different from zero - as turns out to be the case according to the estimates of our baseline model.

Increased enrollment in post-bachelor programs and the missing concern of savings in order to respect the downpayment constraint and then pay the mortgage have strong earnings effects, as shown in Figure 9. In this case, the change takes place mostly on the human capital investment side, as the pattern of savings is mostly unchanged - except for the later years, where a consumption smoothing motive drives workers in the counterfactual exercise into saving more.

Figure 8: Baseline vs. no Homeownership

(a) Liquid Savings

(b) Earnings
7 Policy

7.1 A ”Debt to Equity Swap”: Income Based Repayment

Income Based Repayment plans are a popular solution to broadening access to higher education, as countries like Australia and Great Britain made them their baseline program for student finance (see Chapman (2016)). During recent years, changes to old repayment plans and the creation of new ones have expanded generous income-based repayment options to a growing number of borrowers in the US (Figure 9).

Unlike fixed payment plans, there is no set horizon of loan repayment; instead, the borrower pays 10 percent of discretionary income each month until the loan is paid off or 20 to 25 years pass, in which case the remaining balance is forgiven (but included as taxable income). To be enrolled for these plans, borrowers have to report their income on an annual basis, and meet a series of eligibility criteria.

In this section, an income repayment plan in every period is introduced in the model as a baseline repayment scheme. The income repayment plan is defined to replicate the Pay As You Earn Repayment Plan introduced in 2012: 10 percent of discretionary income for 20 years. At the end of the repayment period, remaining balances are forgiven and the forgiven amount is considered as additional income, to be taxed at a 25% rate.

Figure 9: Evolution of Repayment Plans

Note: Percentage of student loan borrowers enrolled in repayment plans as well as the percentage amount of student debt each repayment plan represents. Includes outstanding principal and interest balances of Direct Loan borrowers in Repayment, Deferment, and Forbearance. Source: Federal Student Aid Data.
We rewrite the recursive problem in (15), as other problems are analogous:

\[ V_{r,t}^B(x,e) = \max_{k',l} \left\{ u(c,s) + \sigma \epsilon_{B,r} + \beta \mathbb{E}[\hat{V}_{r,t+1}^B(x',e')] \right\} \]  

(15)

\[
\begin{align*}
    c + k' + P_r &= (1 + r) \cdot k + 0.9 \cdot w_j(l,h) \\
    h' &= \epsilon' z(h + a((1 - l)h)^{\alpha}) \\
    d' &= (1 + r_d)d - 0.1 \cdot w_j(l,h) \geq 0 \\
    k' &\geq \phi, \ c \geq 0 
\end{align*}
\]

where:

\[
\mathbb{E}[\hat{V}_{t+1}^B(x',e')] = \mathbb{E} \left[ \max \left\{ V_{r,t+1}^B + \sigma \epsilon'_{B,r}, V_{r,t+1}^G + \sigma \epsilon'_{G,r}, V_{o,t+1}^B + \sigma \epsilon'_{B,o} \right\} \right]
\]

A quantitative exercise is necessary to assess the extent to which income based repayment plans moderate the effects of initial student loan debt. On the one hand, enrollment in income driven repayment plans reduces the ratio of student loan payments to monthly wages, increasing disposable income. On the other hand, it can extend the repayment period significantly relative to a 10-year plan, thereby potentially increasing the total interest paid by the student loan borrower over the life of the loan.

The latter effect is the main reason why enrollment under IBR rises, but due mostly to higher enrollment by high ability graduates. However, facing increasing payments during age 25-35, and a small risk of having to pay a lump sum tax in the late 30s because of residual balance forgiveness, workers under IBR delay entry into home ownership even more (see Figure 10). After age 45, income effects start to dominate and overall home ownership grows compared to baseline.

As shown in this section, linking repayment to income does help alleviating financial constraints. Even if the program did not achieve full participation of graduates, the growth in IBR enrollment can be credited with moderating the impact of the dramatic growth in undergraduate debt balances occurred between 2008 and 2016.

### 7.2 Evaluating a Radical Policy: Debt Forgiveness for All

As student debt became a prominent issue in the public debate, various political actors have called for some sort of forgiveness plan. In this chapter we introduce debt forgiveness under a balanced budget constraint, assuming the government can forgive all debt and then finance this program by spreading lump sum taxation over the life cycle of workers. Our exercise wipes out all of undergraduate debt, and replaces it with lump sum taxes levied over the life cycle to keep the reform under a balanced budget.
According to our model, a forgiveness plan would have a large impact on post bachelor enrollment. While adoption of an IBR plan would increase enrollment in post-bachelor plans to 38%, forgiveness would bring it to 44% (see Figure 10). It would both increase overall participation in graduate programs, and do it in particular doing early years. The second effect comes from the disappearance of the delaying motive that induces indebted graduates to postpone enrollment, while the first is a result of the relaxing of borrowing constraints on the same group.

Given larger enrollment, it is not surprising that entry into home ownership is almost unchanged, as income effects move workers in the opposite direction. What happens, in fact, is that there is a small delay in access to home purchases, driven by increased enrollment. The overall impact on earnings and later age home ownership, however, is not substantially larger than under the Income Based Repayment alternative plan.

This comes from the differential impact the two plans have on sorting into graduate school: IBR achieves higher enrollment by a sharp increase in the enrollment of high ability individuals. On the other hand, forgiveness has negative effects on sorting, as it mostly increases the participation of workers with lower learning ability. This has a large impact on endogenous human capital accumulation which is the main driver of earnings growth. Lower ability workers enroll at a higher rate (and borrow for graduate studies), but their net monetary gain is small, and their endogenous human capital investment at age 30-35 is reduced compared to the baseline scenario where they had repaid their residual debt by that age.

Figure 10: Baseline vs. Alternative Repayment Plans
8 Conclusions

What are the implications of higher levels of student debt on life cycle decisions? We find that graduating with higher levels of student debt causes higher earnings right after college, as well as earlier entry into home ownership, but lower income growth in the years after graduation. We then argue that this negative earnings growth is the result of student debt influencing career choices of college graduates. In particular, we find that individuals with higher levels of student debt are less likely to enroll in post bachelor degree programs.

We contribute to the existing literature by arguing that horizon effects determined by preferences for housing are an important channel for obtaining this result. While credit constraints are a necessary ingredient for initial financial conditions to affect life cycle outcomes, their interaction with a strong value attached to homeownership is able to create a wide gap between outcomes of workers that start their careers with different student debt balances.

Several policies have been advocated to help student loan borrowers. However, policy makers need guidance on the type of policies that are likely to be effective, from those that address liquidity constraints of borrowers to policies aimed to forgive a portion of student debt. We contribute to the policy debate by showing the merits of two alternative proposals. One, that is redistributive in nature, is to operate with a widespread forgiveness plan of all undergraduate debt, financed by lump sum taxes to be repayed over an extended period of time by the same cohort whose debt was forgiven.

The other, that resembles closely the path chosen so far, aims at alleviating the burden of student debt by linking repayments to earnings. We show that an extension of existing policies is able to achieve results that are quantitatively very similar to more ambitious forgiveness programs - namely, that the income based repayment plans that already attract a significant number of graduates are already an effective policy to reduce career and human capital accumulation distortions induced by student borrowing.

In future work, we plan to move in two directions. The first is to endogenize the college borrowing decision, by modeling undergraduate attendance, and nest our life cycle structure into a general equilibrium framework. This extension will allow us to investigate the pattern of increased college attendance of the last decades, identifying its causes among shifts in technology, preferences and policy. After doing that, we will aim at comparing more comprehensive policies regarding education financing, human capital, and life cycle decisions.

Another important question to address requires extending the housing decision part of the model to allow for location choice. The decline of interstate migration in the U.S. has long been associated with reduced labor market dynamism, although recent research pointed at it resulting from a reduction of the component of occupation specific human capital. In presence of location choices, housing becomes not only an investment, but can also a drag or an obstacle to geographical and labor mobility. Changes in labor markets can thus have interactions with financial constraints, and generate interesting macroeconomic implications.

Appendix 1. Data

In this section we describe in more detail the data sources for the variables covered in Section 3.

A1.a B&B data

We use the restricted-use data and keep observations that have a positive value in the weight variable wte000, which represents the students who received a bachelor’s degree in the 2007-08 academic year and responded to all interviews (2007-08, 2009, and 2012). The sample includes approximately 14,500 college graduates. We use and modify the following variables (available for public-use online in https://nces.ed.gov/datalab/powerstats):

Debt:
Cumulative loan amount borrowed for undergraduate through 2007-08 (b1borat): Indicates the cumulative amount borrowed from all sources for the respondent’s undergraduate education through June 30, 2008. Does not include Parent PLUS loans. We log-transform this variable and deal with zero values by adding $1.

Post College outcomes:
2012 Current Primary Job Salary (b2cjsal): Indicates the respondent’s annualized salary from their current or most recent primary job. Primary job is defined as the respondent’s current or most recent job that lasted more than 3 months. We replace with a zero value the earnings of those who were not working at the time of the interview but reported the most recent earnings. We log-transform this variable and deal with zero values by adding $1.
2009 Current Primary Job Salary (b1erninc): Indicates the respondent’s income from their current job as of the B&B:09 interview. For respondents with multiple jobs, salary is only for the primary job, the job at which the respondent worked the most hours. We log-transform this variable and deal with zero values by adding $1.
2012 Primary Job: Occupation (b2cjocc33): Indicates the occupation in which the respondent reported working in their current or most recent primary job as of the BB:12 interview, using 33 categories, based on the 2010 Standard Occupational Classification system developed by the Bureau of Labor Statistics. Primary job is defined as the respondent’s current or most recent job that lasted more than 3 months; if more than one job meets these criteria, the job with the highest number of hours per week is selected. Variable categories are: Agriculture occupations; Air transportation professionals; Artists and designers; Business managers; Business occupations (non-management)...and Transport support occupations.
2012 Current Value of Primary Residence (b2fhomval): Indicates the approximate current value of the respondent’s home(s), as reported by the respondent in the B&B:12 interview. We classify as home owners those observations with a value higher than zero. For the value of the house, we consider houses with a value higher than $100,000 and log-transform the variable.
Highest degree attained since bachelor’s as of 2012 (b2hideg): Identifies the highest postsecondary degree or certificate the respondent had obtained after completing the 2007-08 bachelor’s degree, as of the BB:12 interview. Variable categories are: Did not earn degree, Undergraduate certificate or diploma, Associate’s degree, Additional bachelor’s degree, Post-baccalaureate certificate...and Doctoral degree - other.

College Fixed Effects:
Institution Sector in 2007/08 (sector4): Indicates the sector of the 2007-08 bachelor’s degree-granting institution, using five categories. Variable categories are: Public 4-year, Private nonprofit 4-year, Public 2-year, For-profit, and Others or attended more than one institution. WE keep Public 4-year and Private nonprofit 4-year colleges.
Carnegie code (2005 basic, collapsed) for 2007-08 institution (cc2005c): Indicates the Carnegie basic institution classification code, using collapsed categories, of the 2007-08 bachelor’s degree-granting institution. Variable categories are: Associate’s, Research and doctoral, Master’s, Baccalaureate, and Special focus and other. We drop Associate’s and Special focus and other institutions.

Individual Controls:
Date of first postsecondary enrollment (pse_date): Identifies the year and month, in YYYYMM format, when the respondent first enrolled in postsecondary education. We keep those students that

**Expected Family Contribution in 2007-08 (efc):** Indicates the composite estimate of the federal expected family contribution (EFC) used in 2007-08 need analysis.

**Dependency status in 2007/2008 (depend):** Indicates the respondent’s dependency status during the 2007-08 academic year. Variable categories are: Dependent and Independent.

**SAT I score (tesatder):** Indicates the respondent’s SAT I combined score, derived as either the sum of SAT I verbal and math scores or the ACT composite score converted to an estimated SAT I combined score using a concordance table from the following source: Dorans, N.J. (1999). Correspondences Between ACT and SAT I Scores (College Board Report No. 99-1).

**Field of Study (majors4y):** Indicates the respondent’s major or field of study, using 10 categories, for the 2007-08 bachelor’s degree. Variable categories are: Computer and information sciences; Engineering and engineering technology; Bio and phys science, sci tech, math, agriculture; General studies and other; Social Sciences, Humanities, Health-care, Business, Education and Other Applied. We classify them in three categories: STEM and health-care, Social Sciences and Business, Other.

**Race/Ethnicity (race):** Indicates the respondent’s race/ethnicity with Hispanic or Latino origin as a separate category. Variable categories are: White, Black or African American, Hispanic or Latino, Asian, American Indian or Alaska Native, Native Hawaiian, other and More than one race. We classify them into four categories: White, Black, Latino, Asian, Other.

**Gender (gender):** Indicates the respondent’s sex. Variable categories are: Male and Female.

### A1.b IPEDS data

Using harmonized college identifiers, we merge the B&B individual level data with institution level from the Institutional Post-Secondary Database (IPEDS). We use the IPEDS data in order to get information about the cost of attendance as well as the amount of grants and loans at the institutional level. We use the following variables for 2004-2007 from the IPEDS data center:

**College Student Debt:**

**Average amount of student loans awarded to full-time first-time undergraduates (loan):** Any monies that must be repaid to the lending institution for which the student is the designated borrower. Includes all Title IV subsidized and unsubsidized loans and all institutionally- and privately-sponsored loans. Does not include PLUS and other loans made directly to parents.

**Percent of full-time first-time undergraduates awarded student loans (ploan):** Percentage of full-time, first-time degree/certificate-seeking undergraduate students who were awarded student loans.

**Institutional Grants:**

**Average amount of institutional grant aid awarded to full-time first-time undergraduates (grant):** Scholarships and fellowships granted and funded by the institution and/or individual departments within the institution, (i.e., instruction, research, public service) that may contribute indirectly to the enhancement of these programs.

**Percent of full-time first-time undergraduates awarded institutional grant aid (pgrant):** Percentage of full-time, first-time degree/certificate-seeking undergraduate students who were awarded institutional grants (scholarships/fellowships).

**Grant-to-Aid:**

Some of the institutions have a missing value in grants or loans and at the same time the percentage of students who were awarded grants or loans is zero. We substitute these observations with a zero value in grants or loans. We then drop all colleges with a grant-to-aid of 0 or 100 in any of the six years (2002-2007). Given that the average sum (and percent) of institutional grant and loan amounts are not available for 2002-2007, we construct the total institutional grant-to-aid ratio in the following way:

\[
aid_{j,t} = ploan_{j,t} \cdot loan_{j,t} + pgrant_{j,t} \cdot grant_{j,t} = \left( \frac{\text{TotalDebt}_{j,t}}{\text{Indebted}_{j,t}} \right) \left( \frac{\text{Indebted}_{j,t}}{\text{Students}_{j,t}} \right) + \left( \frac{\text{Grant}_{j,t}}{\text{Recipient}_{j,t}} \right) \left( \frac{\text{Recipient}_{j,t}}{\text{Students}_{j,t}} \right)
\]

\[
x_{j,t} = \frac{\left( \frac{\text{Grant}_{j,t}}{\text{Recipient}_{j,t}} \right) \left( \frac{\text{Recipient}_{j,t}}{\text{Students}_{j,t}} \right)}{aid_{j,t}}
\]

A1.c Home-Ownership Across Cohorts

Figure 12: Evolution of First-Time Home-Ownership by Cohorts

Appendix 2. Solution Method

A2.a Discrete-Continuous Choices

We illustrate how we take into account discrete choices with the problem of an employed renter with student loans, as in the Bellman Equation (15). For illustrative purposes only, we assume no borrowing constraints. If the worker had no discrete choices to make, the Bellman equation for the optimal consumption of a worker would satisfy the following first order condition known as the Euler equation:

$$0 = u'_c(c, s) - \beta(1 + r)E(u'_c(c', s'))$$

(1)

However, since at any period the renter worker can choose two discrete choices (to become a homeowner or switch career), the problem at the state vector point \(\{a, h, j, d, e, t\}\) involves solving for all the possible combinations of available discrete choices.

Following Iskakov et al. (2017), we assume instead that the discrete choices are affected by choice-specific taste shocks, \(\sigma \in \varepsilon\), i.i.d. Extreme Value type I distributed with scale parameter \(\sigma_\varepsilon\) as in McFadden et al. (1973).

Taking again the value function in (15). Abstracting from career and repayment choice, and focusing only on the home-ownership decision, the expected value of the future value function becomes:

$$\mathbb{E}[V'] = \max \mathbb{E}[V_t(k', h', j', m', d', e', t + 1)], \mathbb{E}[V_{o, \lambda}(k', h', j', m', d', e', t + 1)] =$$

$$= \max \mathbb{E}[V_t(\cdot, t + 1) + \sigma_\varepsilon \varepsilon(o)], \mathbb{E}[V_{o, \lambda}(\cdot, t + 1) + \sigma_\varepsilon (r)] =$$

$$= \sigma_\varepsilon \log (\exp\{V_t(\cdot, t + 1)/\sigma_\varepsilon\} + \exp\{V_{o, \lambda}(\cdot, t + 1)/\sigma_\varepsilon\})$$

(2)

Thus, the Euler equation for a renter can then be written as:

$$0 = u'_c(c, s) - \beta(1 + r)\mathbb{E}\left[u'_c(c', s' > 1) \cdot P(s' > 1|k', h', j', m', d', e') + u'_c(c', s' = 1) \cdot P(s' = 1|k', h', j', m', d', e')\right]$$

(3)

where \(P(s' > 1)\) and \(P(s' = 1)\) are conditional choice probabilities given by the binomial logit formula:

$$P(s' > 1|k', h', j', m', d', e') = \frac{\exp\{V_{o, \lambda}(\cdot, t + 1)/\sigma_\varepsilon\}}{\exp\{V_{o, \lambda}(\cdot, t + 1)/\sigma_\varepsilon\} + \exp\{V_t(\cdot, t + 1)/\sigma_\varepsilon\}}$$

$$P(s' = 1|k', h', j', m', d', e') = \frac{\exp\{V_t(\cdot, t + 1)/\sigma_\varepsilon\}}{\exp\{V_{o, \lambda}(\cdot, t + 1)/\sigma_\varepsilon\} + \exp\{V_t(\cdot, t + 1)/\sigma_\varepsilon\}}$$

(4)

A2.b Borrowing constraints

Solving (2) requires taking care of an additional issue. Formally, given the state \(S\) and indicating the Euler equation as \(\phi : S \times \mathbb{R}^m \to \mathbb{R}\), and the policy function as \(k' : S \times \mathbb{R}^m \to \mathbb{R}\), one needs to find policy and multiplier \((k', \mu) \in \mathbb{R} \times \mathbb{R}\) s.t.

$$\phi(S, k', \mu) = 0, k' \geq \phi \perp \mu \geq 0$$

(5)

Following Garcia and Zangwill (1981), this problem can be transformed into a system of two equations, and can then be solved using standard solution algorithms for root finding.

Define a variable \(\alpha\) such that:

$$\alpha \equiv \begin{cases} \mu, & \text{if } \mu \geq 0, k' = \phi \\ -k', & \text{if } \mu = 0, k' \geq \phi \end{cases}$$

(6)

and
\[ \alpha^+ = (\max(0, \alpha))^k \]
\[ \alpha^- = (\max(0, -\alpha))^k \] (7)

where \( k \in \mathbb{N}^+ \). The variable acts like a "penalty" when the constraint is violated, forcing the algorithm to search in the feasible set. The problem can be rewritten as finding policies and \( \alpha \) such that:

\[ \phi(S, k', \alpha^+) = 0 \ , \ k' - \alpha^- = 0 \] (8)
Appendix 3. Optimal Weight Matrix for GMM

We follow Erickson and Whited (2002) in computing the optimal weight matrix $\hat{\Omega}^{-1}$ from the following formula for clustered covariance:

$$
\hat{\Omega} = \frac{1}{nT} \sum_{i=1}^{n} \left( \sum_{t=1}^{T} \psi_{h(x_{i,t})} \right) \left( \sum_{t=1}^{T} \psi_{h(x_{i,t})} \right)'
$$

(9)

in which $\psi_{h(x_{i,t})}$ is the vector of influence functions for the empirical moments $h(x_{i,t})$. Deriving the influence functions for choice of moments is relatively straightforward. Take any subset of $h(x_{i,t})$ and denote it as $\theta$. For those moments that are obtained from simple averages, i.e. $\theta = E(x_i)$, the influence function can be computed simply as:

$$
\psi_{\theta}(x) = x - E(X)
$$

(10)

In the case of linear regression coefficients, we need to get influence function for the slope and the constant. The slope is $\hat{\beta}(\beta) = \frac{COV(X,Y)}{VAR(X)}$. Then:

$$
\psi_{\hat{\beta}(\beta)}(x, y) = \frac{(x - E(X))(y - E(Y)) - COV(X,Y)}{VAR(X)} = \frac{(x - E(X))^2 - VAR(X)}{(VAR(X))^2} \frac{COV(X,Y)}{VAR(X)}
$$

(11)

The constant is instead $\hat{\alpha} = E(y) - \frac{COV(X,Y)}{VAR(X)} E(x) = E(y) - \frac{E(X)E(Y) - (E(X))^2E(Y)}{VAR(X)}$. Then:

$$
\psi_{\hat{\alpha}(\alpha)}(x, y) = \frac{(xy - E(X)Y)E(X) + (x - E(X))E(X) - (y - E(Y))(E(X))^2 - 2(x - E(X))E(X)E(Y)}{VAR(X)}
$$

$$
+ \frac{y - E(Y) + ((x - E(X))^2 - VAR(X)) (E(X)E(Y) - (E(X))^2E(Y))}{(VAR(X))^2} = y - E(Y) -
$$

$$
\frac{(xy - yE(X))E(X) + (x - E(X))E(X)(COV(XY) - E(X)E(Y))}{VAR(X)} - \frac{(x - E(X))^2 - VAR(X)}{(VAR(X))^2}
$$

(12)

Finally, we use the ratio of regression coefficients. Take the ratio of slopes $\hat{\beta}_y/\hat{\beta}_b$. Then by the chain rule:

$$
\psi_{\hat{\beta}_y/\hat{\beta}_b}(x_y, y_y, x_b, y_b) = \frac{\psi_{\hat{\beta}(\alpha)}(x_y, y_y)\hat{\beta}_b - \psi_{\hat{\beta}(\alpha)}(x_b, y_b)\hat{\beta}_b}{\hat{\beta}_b}
$$

(13)

And similarly, one can obtain the influence function for the ratio of constants.
Appendix 4. Model without heterogeneity in ability

We estimate the same model as in Section 5, assuming no heterogeneity in ability.
